

htmlDesktop

This is a tool for digital props, used for movies and television, to easily emulate different operating systems on different operating systems. This circumvents the need for the real system to be properly prepared and stripped of everything that is not wanted.

Available right now are "clones" of Windows 10, mac OS Big Sur and some Linux-like distro.

These clones are not very accurate; and the goal in the end is to differentiate them enough that no copyright problems occur when displayed on commercial productions.

This repo is just the boilerplate for everything special that needs to be done to tell a story.

Customizing needs to be done onto the workstations, the browser, etc, to be ready for production.

How this works

Workstations

Workstations are, as the name implies, different computer setups for different scenes and/or characters. They include styling (like the OS used, the desktop image, system Colors etc) and positions of open or minimized windows or programs.

See [here](#) for everything about setting up new workstations.

States

Local saving and loading is possible by using the browsers localStorage. Based off the workstations, you can further adjust and set up different variations of any workstation. You load up a workstation, adjust to the scenes needs, save it.

When filming, the actress or actor can fool around. After the take, you reload the last state to start anew.

These scenes are by design local to the machine that you're using, so changes saved like this are not shared across different computers. They can be exported, shared and imported though.

Display locally & offline

To display this locally and without an internet connection, there is a [container app](#) in development for Windows, Mac and Linux (including raspberry pi's).

To use this app, you need to clone this repo and use your own version of it to have your own workstations loaded into the app.
